

# Oil & Gas

## Introduction

This Environmental and Social Risk Briefing covers the oil and gas industry from exploration to production to refining to retail. It includes natural and petroleum gas, fuel oils, petrochemicals, lubricants, petroleum and other by-products as well as the emerging market of bio fuels (biodiesel).

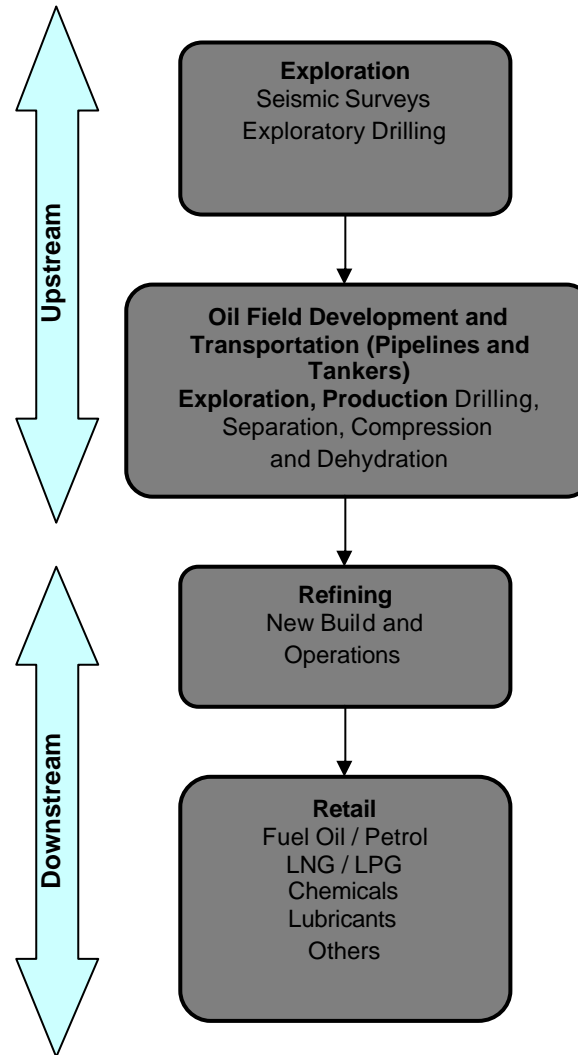

## Oil and Gas

Oil and gas are natural products created by the degradation of organic material in geological deposits within the earth's surface. They are made up of mixtures of thousands of organic substances, which once processed provide a very adaptable commodity from fossil fuels to a variety of petrochemicals.

The oil and gas sector is split into upstream and downstream activities. The upstream industry includes exploration and production and transfer of oil and gas to the refining or processing facility. The downstream industry involves the production (including refining), distribution and sale of refined hydrocarbon products as illustrated below.

Oil and gas projects can be onshore (terrestrial) or offshore (marine) or a combination of both at a variety of scales and may transect international boundaries.

## Oil and Gas Life Cycle

## Exploration

Oil and gas, historically, was recovered as crude oil and natural gas from natural reservoirs contained within sedimentary rocks. Recent advances in production technologies and the upturn in petroleum prices have enabled alternative hydrocarbon reservoirs to now also be exploited (e.g. tar sands, oil shale and biomass (vegetable materials)).

Exploration includes identifying likely geological reservoirs based on intrusive (drilling) or non-intrusive (seismic) surveying techniques. Exploration fields are typically large areas, may be terrestrial or marine or both and may span international boundaries or non-territorial waters. Exploration evaluates the potential for oil and gas bearing strata, enables an estimate of the reserves present to be made and gains an understanding of the quality of the oil and gas contained within the reservoir.

## Production

Once a commercially viable reserve has been identified, oil and gas is extracted by drilling production wells into the reserve using highly specialised technologies. A variety of synthetic or natural drill fluids are used to keep the drill bit cool and lubricated and to bring drill cuttings to the surface.

# Oil & Gas

Oil is either pumped or pressure forced to the surface. Natural gases may be re-circulated to increase oil recovery rates. Water or steam flooding (including the use of potentially hazardous chemicals) of the reserve is commonly completed to induce movement of oil in the reservoir. The permeability of the bedrock (and hence recovery rate of oil and gas) may also be improved by fracturing using explosives or water, with a variety of chemical additives, at high pressure. Acids and other compounds are typically injected to prevent clogging. When extracting oil and gas from the excess gasses are typically flared off to atmosphere.

Extracted hydrocarbon product is separated in to gas and liquids and dehydrated to remove excess water. Oil and gas extraction fields are often exploited using a network of extraction wells feeding individual processing and handling plants. The infrastructure to manage and distribute the extracted oil and gas may be widespread including a variety of flaring points.

Tar sands and oil shales are shallow surface geological strata that can be processed to release heavy crude. Only recently has this processing become economic, as the technique requires the large-scale excavation of solid material and energy intensive thermal processing sometimes with steam and ultrasonic techniques.

## *Refining*

Once extracted, oil and gas are processed to form a consistent saleable product, or more typically, split in to a variety of different products.

Oil refining involves two types of processing: the physical separation of the raw material and the subsequent chemical refinement of this raw material into different petroleum products (called fractions).

Crude oil and gas undergoes primary separation by distillation to yield a range of different fractions including gases, naphtha, paraffin and gas oil. The production of different products is dependent upon the composition of the crude oil (raw material), the technology of the refinery (principally a distillation process) and market demand. The types and amount of product can be adapted to market requirements by secondary conversion processes that use heat, catalysts and hydrogen. This is called "cracking" and breaks down heavy fractions into lighter fractions such as gas oil and petroleum spirit.

Refineries use a large number of chemicals and additives in their process plants and for blending into the finished products. Some of these may be classified as potential contaminants including metals, metal compounds, organic and inorganic acids, caustic and laboratory chemicals, lead

compounds, oxygenates (used as octane enhancers) and solvents.

Refineries include crude receiving facilities, distillation and cracking plant with a variety of ancillary treatment processes. A typical refinery will also include provision for the storage of crude and finished product as well as a distribution network.

## *Petrochemicals*

The production of petrochemicals requires the synthesis of refined raw products such as ethylene referred to as "precursors". These precursors are further distilled, converted, cracked or reformed to produce a chemical of choice. The infrastructure for petrochemical production involves a significant chain of heating, cooling, hydrating and chemical addition.

## *Liquefied Natural Gas (LNG)*

In order to cost effectively distribute natural gas where pipelines do not exist, it is first processed to remove impurities and recoverable hydrocarbons and then liquefied to reduce the volume of gas for transport. Transportation is undertaken in bespoke vehicles (typically ships) and moved from a LNG processing plant to a receiving or re-gasification plant. Gas is condensed in to a liquid at atmospheric pressure by cooling to temperatures  $-120^{\circ}\text{C}$  to  $-170^{\circ}\text{C}$ . A typical LNG

# Oil & Gas

plant consists of at least one liquefaction train that includes gas receiving and cooling plant. Significant distribution infrastructure such as ports and loading gantries are required for LNG and re-gasification plants.

## *Biodiesels*

Biodiesels are produced from a variety of biological sources such as vegetable oils and animal fats. The most common production sources are from vegetable crops such as rape and soya bean. Once harvested, the crops are pressed to release the vegetable oils and this oil is refined to produce an economic fuel.

## *Transportation*

The distribution of crude and refined hydrocarbons requires a significant infrastructure that typically requires trans-boundary shipments; pipeline, boat or tanker may transport oil and gas.

Pipelines transport natural fuels such as oil and gas and can be located above or below the ground or seabed. They can range in size up to two meters in diameter and range from several to hundreds of kilometres in length over a path known as the pipeline Right of Way (ROW). Overland and near-shore pipelines are usually buried while offshore pipelines are generally located on the seabed. Pipelines may transport unrefined oil or gas from a

wellhead to transfer or processing facilities, or refined oil and gas to an end user (e.g. a petrochemical or power plant). A pipeline is not confined to the pipe itself rather include ancillary facilities such as receiving dispatch, pump and control stations; access or maintenance roads, booster stations (required at regular intervals for long distances to cope with internal friction changes in elevation along the line) and compression stations (to maintain pipeline pressure at regular intervals).

LNG is transported by specially designed vessels and stored in specially designed refrigerated tanks. There are a variety of international standards for the design of oil and gas shipping vessels following the well-documented Exxon Valdez oil spills and others from oil tankers at sea.

## *Retail and Distribution*

Following processing, oil and gas is distributed to bulk fuel storage facilities typically via pipeline. These dedicated facilities will typically be located at strategic logistical hubs to enable ease of distribution to the customer. These "terminals" will have infrastructures to receive and distribute fuels. Fuel is typically transferred from the terminal to road tanker for delivery to the forecourt. Petrochemicals are typically containerised or tankered to the customer in specialist vessels. LPG is typically distributed in

dedicated gas canisters for immediate use. Natural gas may be piped directly to the customer from a bulk storage gasometer.

Processed fuel is stored in either above ground or underground storage tanks (AST and UST respectively). These tanks are now required to have dedicated containment measures to control spills or accidental releases. Most modern tanks are double skinned and fitted with alarms to warn when leaks are occurring. Older tanks however, are unlikely to incorporate such systems but may have wet stock reconciliation records compiled through manual dip readings of tank contents.

Large distribution networks may exist in the oil and gas industry including significant portfolios of retail petroleum stations. Given the large volume and variety of distribution networks, significant management of environmental impacts may be required.

# Oil & Gas

## Key Sector Risks and Headline Issues

In large-scale oil and gas operations some critical issues of particular public concern may result in reputation or credit risk to a lender or an investor, these include:

- ♦ Coastal and marine ecology - impact on corals and marine biodiversity from offshore and coastal operations and tankers (spills);
- ♦ Climate change - finite fossils fuel resources, long term impact from ozone depletion and global warming from greenhouse gas emissions from refining and processing;
- ♦ Security of supply and operations and human rights violations of workers and communities - child labour, terrorism and sabotage, social conflict and unrest;
- ♦ Revenue transparency - bribery and corruption particularly in developing economies and states with weak governance structures;
- ♦ Sustainable community development - exporting of fuels and revenues from energy poor communities, economic dependency of project affected communities at project closure; and
- ♦ Health and safety and environmental risks of major explosions, leaks or spills.
- ♦ Destruction or irreversible impacts on critical habitats (this would include: rainforests, coastal and marine ecology and any protected areas (wetlands, etc.)
- ♦ Involuntary resettlement / displacement of peoples as a result of project activities
- ♦ Community health and safety - spread of diseases, prostitution, managing HIV/AIDS, etc.
- ♦ Impacts on vulnerable people (the poor, indigenous, women, children - the disadvantaged)

The following tables detail potential environmental and social risks associated with industry processes and appropriate control measures. These may include **Environmental and Social Management Plans** and may form part of a wider **Environmental Social Management System**.

# Oil & Gas

## Key Considerations

1. Does the process require authorisation, and if so has this been obtained?
2. Are there any outstanding legal actions or prosecutions relating to the plant, including problems of public nuisance such as odour, which may become a liability?
3. How old are the refinery works? (Pollution will be greater in older works).
4. Has on-site disposal of process by-products and wastes taken place?
5. How is effluent and/or process wastewater controlled?
6. Are any materials used or produced subject to environmental phase out or reduction agreements?
7. Have decommissioning options been assessed if required, and have costs been fully accounted for and independently confirmed as adequate?
8. What contingency plans are in place to deal with spillage, leaks, etc?
9. Is the company diversifying into alternative fuels and renewable energy?
10. For new sites/extension projects has an Environmental Impact Assessment been commissioned to assess the environmental impacts?

# Oil & Gas

## Regulation and Best Practice

Permits, consents and licences are likely to be required for oil and gas operations, the specifics of which will depend on the jurisdictional framework in the geographical location of a given project. In developing regions, weaker governance structures may mean that there is less stringent implementation of local controls and regulations or indeed there may be no controls at all. In such cases the project proponent of best practice should ideally adhere to international environmental and social standards and industry Best Practice.

In the case of almost all large-scale new build, expansion and development projects an Environmental and Social Impact Assessment (ESIA) will be required particularly where project debt financing is being sought. A comprehensive ESIA undertaken to international standards allows both the project sponsor and the investors to assess the full range of potential environmental and social impacts related to a project development, operation and decommissioning. Part of the ESIA process is to design appropriate mitigation measures and to set a framework for the monitoring the performance of these measures on a long-term basis. This limits and controls compliance and remediation costs as well as long term credit and reputation risks.

For smaller scale projects and operations a full ESIA may not be required. Focused studies on particular issues of concern may however, be helpful in identifying potential environmental and social risks associated with certain project activities.

The table below lists key international standards and publicly available best practice reference materials relevant to the oil and gas industry.
